

Political news coverage of online news

...

Franziska Löw*

November 2020

I Introduction

In democracies, the media fulfill fundamental functions: They should inform the people, contribute to the formation of opinion through criticism and discussion and thus enable participation. In recent decades, however, concern has grown about the role of the media in politics in general and in election campaigns in particular. They are criticized for influencing election results through their reporting and for helping populist parties in particular to flourish. After the 2017 federal elections in Germany, for example, the media were accused of contributing to the success of the right-wing populist AfD by increasingly including the party's content and using the same language in their articles as the AfD. Representatives of these media houses strongly opposed this accusation. The purpose of this study is to examine whether there is evidence that supports the accusation of biased media reporting, especially during election campaigns.

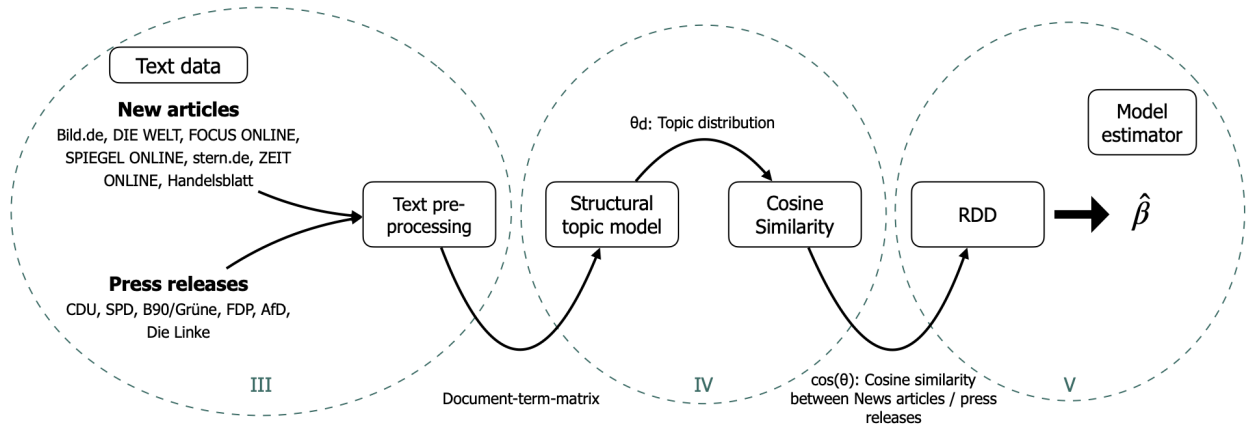

For advertising-financed media the battle for the attention of the recipients is at the center of economic decisions. Online media in particular, which offer their content to a large extent free of charge and generate their revenue through advertising space, compete for the scarce resource of attention. Consumers pay a non-monetary price providing their attention, which the media platform bundles and sells on to advertising customers. This business model corresponds to that of a platform market, in which media companies act as platforms that connect the market of advertising with the reader market to exploit the indirect network effects between them (Dewenter and Rösch 2014). A profit-maximizing publisher therefore directs its economic decisions according to what will attract the most attention.

This conclusion, derived from the economic theory of platform markets, corresponds to the notion of media logic, a central concept in the field of media and communication studies (Takens et al. 2013). The debate about media logic is embedded in the broader discussion about the interaction between the press, politics and the public. The underlying thesis is that the content of political news is the product of news values and narrative techniques that media use to attract audiences (Strömbäck 2008). According to Takens et al. (2013), three content attributes highly correspond with news values and influence how journalists interpret political events: 1) personalized content, i.e., the focus on individual politicians; 2) the framing of politics as a contest and 3) negative coverage. Similarly Blassnig et al. (2019) states that media primarily focus on news factors, i.e. the factors that turn an event into news worth reporting like conflict, drama, negativity, surprise or proximity. Likewise populist messages often co-occur with negative, emotionalized, or dramatized communication style, thus utilizing similar mechanisms as the media logic, respectively the attention economy. In fact, Blassnig et al. (2019) shows that populist key messages by political and media actors in news articles provoke more reader comments under these articles. Media competing for the attention of readers therefore have an incentive to pick up on the key messages of these parties. These, in turn, benefit from being able to place their agendas in the public debate (Druckman and Parkin (2005), Eberl (2018)). It is assumed, that smaller, non-established parties in particular benefit from placing their topics in the media in order to get them into the voters' heads. Here, the tendency of the reporting is irrelevant but rather the quantity is decisive.

*Institut für Industrieökonomik, Helmut Schmidt Universität. Email: .

However, the causal relationship between reporting and voter preferences is not the subject of this study. Rather, it is intended to measure how online news coverage coincides with the messaging of different political parties. Especially during election campaigns political parties want the media agenda to be congruent with their own agenda to define the issue-based criteria on which they will be evaluated by voters (Eberl, Boomgaarden, and Wagner 2017). Parties instrumentalize their public relations in order to highlight issues that they are perceived to be competent on, that they “own” and that are important to their voters (Kepplinger and Maurer 2004). This paper therefore analyzes the period before and after the 2017 federal elections in Germany to answer the question whether political news report about similar topics and if this similarity changes after the election campaign is over.

In order to answer these and other media-related questions in the political context, quantifying the content of media is a prerequisite. One of the key challenges is to determine the features that are used to describe media content - be it audio, video or text content. Studies that rely on quantifying media content for their analyses use, for example, visibility (how often political actors appear in the media) or tonality (how they are evaluated). Other studies examine the topics discussed or the language used in the media, in order to identify whether political actors are able to place their own policy positions in the media. Leading studies from economic literature, for example, examine how often a newspaper quotes the same think tanks (Groseclose and Milyo (2005), Lott and Hassett (2014)) or uses the same language (M. A. Gentzkow and Shapiro 2004) as members of Congress. Following this approach, the present paper compares topics discussed in media outlets with topics addressed in the press releases of the parties in the German “Bundestag,” to measure the content similarity between online news and parties press releases.¹ To discover the latent topics in the corpus of text data, the structural topic model (STM) developed by M. E. Roberts, Stewart, and Airoldi (2016) is applied. This probabilistic text model results in a probability distribution for each document across all topics, which is then aggregated to calculate the degree of difference between the news articles of different media providers and the press releases of the parties using a linear regression model.

II Background information

¹For the sake of simplicity, both news articles and press releases will be referred to as documents in the following.

The political situation in Germany (June 2017 - March 2018)

The articles analyzed in this paper cover a period from June 1, 2017 to March 1, 2018 and thus cover both the most important election campaign topics for the Bundestag elections on September 24, 2017 and the process of forming a government that lasted until February 2018. After four years in a grand coalition with the Social Democrats (SPD), German Chancellor Angela Merkel, member of the conservative party CDU/CSU (also known as Union), ran for re-election. The SPD nominated Martin Schulz as their candidate.

On the right side of the political spectrum, AfD (alternative for Germany) managed to be elected to the German Bundestag for the first time in 2017. The political debate about the high refugee numbers of the past years brought a political upswing to the AfD, which used the dissatisfaction of parts of the population to raise its own profile. In the course of the reporting on the federal elections, leading party members of the AfD as well as party supporters repeatedly accused the mass media of reporting unilaterally and intentionally presenting the AfD badly.

After the election, the formation of a government was difficult due to the large number of parties elected to the Bundestag and the considerable loss of votes by the major parties CDU/CSU and SPD. Since all parties rejected a coalition with the AfD, numerically only two coalitions with an absolute parliamentary majority were possible: a grand coalition (“GroKo” - from the German word Große Koalition) of CDU/CSU and SPD, and a Jamaica coalition (coalition of CDU/CSU, FDP (economic liberal party) and B90/Die Grünen (Bündnis 90/Die Grünen, green party)). The grand coalition was initially rejected by the SPD. The four-week exploratory talks on the possible formation of a Jamaica coalition officially failed on November 19, 2017 after the FDP announced its withdrawal from the negotiations. FDP party leader Christian Lindner said that there had been no trust between the parties during the negotiations. The main points of contention were climate and refugee policy. CDU and CSU regretted this result, while B90/Die Grünen sharply criticized the liberals’ withdrawal. The then Green leader Cem Özdemir accused the FDP of lacking the will to reach an agreement.

After the failure of the Jamaica coalition talks, a possible re-election or a minority government as alternatives were discussed in the media before the SPD decided to hold coalition talks with the CDU/CSU. This led to great resistance from the party base, which called for a party-internal referendum on a grand coalition. After the party members voted in favor of the grand coalition, a government was formed 171 days after the federal elections.

Figure 1 shows that support for the two major popular parties has been declining in recent months since August 2017, with the CDU/CSU again showing positive survey results since November 2017.² However, the poll results of the SPD have been falling since March 2017. At the same time, the AfD in particular has been recording increasingly positive survey results since June 2017.

Figure 1: Election polls during the period under review

²For each party the survey results of the seven major institutes are considered. To calculate a smooth line for each party on each day, the moving average within 15 days (7 before the day, 7 after the day, and the day itself) is estimated. The data source is <https://www.wahlrecht.de/>.

German online news market

The analysis performed in this paper is based on the news articles of the following news websites: Bild.de, DIE WELT, FOCUS ONLINE, Handelsblatt, SPIEGEL ONLINE, stern.de, ZEIT ONLINE. As can be seen from Figure 2(a), expect for Handelsblatt (position 53), these media outlets are among the top 30 German online news providers in the period under review in terms of visits.³

The main source of income for these privately managed media houses is digital advertising, even though paid content is playing an increasingly important role. However, according to a survey on digital news by the Reuters Institute (N. Newman et al. 2018) only 8% of respondents pay for online news. The online survey for German data was undertaken between 19th - 22nd January 2018 by the Hans Bredow Institute⁴ with a total sample size of 2038 adults (aged 18+) who access news once a month or more. Among other questions, participants were asked which news sources they use to access news online.⁵ The results displayed in Figure 2(b) indicate that the media used for the analysis play a relevant role in their consumption.

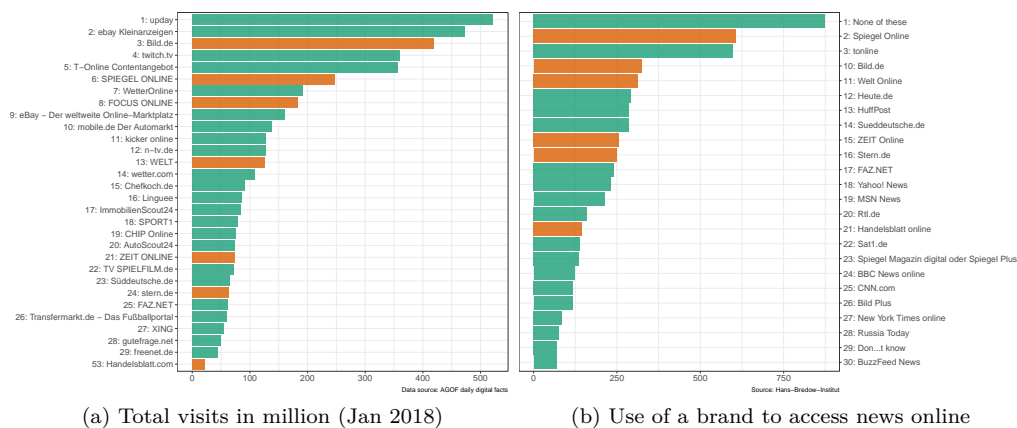

Figure 2: Selected German news brands

III Text data

I conduct the estimation on a sample of 18,757 online news articles from the seven German news providers described in the previous section⁶ about domestic politics and press releases of the seven parties that have been in the Bundestag since the 2017 federal elections⁷. Both news articles and press releases are dated from June 1, 2017 to March 1, 2018.

News articles scraped from the Webhose.io API.⁸ In order to consider only news about national politics, the articles were filtered based on their URL. The press releases were scraped from the public websites of the political parties and parliamentary groups using an automated script.⁹

Figure 3 shows the distribution of the number of articles by date and media outlet. There is a high peak around the federal elections on September, 24th and another one shortly after the failure of the Jamaica coalition talks on November, 19th (indicated by the red dotted lines).¹⁰ Furthermore, Figure 3 shows that

³The term visit is used to describe the call to a website by a visitor. The visit begins as soon as a user generates a page impression (PI) within an offer and each additional PI, which the user generates within the offer, belongs to this visit.

⁴<https://www.hans-bredow-institut.de/de/projekte/reuters-institute-digital-news-survey>

⁵The exact question was: "Which of the following brands have you used to access news online in the last week (via websites, apps, social media, and other forms of Internet access)? Please select all that apply."

⁶Bild.de, DIE WELT, FOCUS ONLINE, SPIEGEL ONLINE, stern.de, ZEIT ONLINE, Handelsblatt

⁷CDU, SPD, B90/Grüne, FDP, AfD, Die Linke

⁸For more information see <https://docs.webhose.io/reference#about-webhose>.

⁹The scraping code was written in R and can be made available on request.

¹⁰The peak in July especially for stern.de is due to increased reporting about the G20 summit in Hamburg.

DIE WELT published the most articles on domestic policy, followed by stern.de, Handelsblatt and FOCUS ONLINE.

Figure 3: Distribution of news articles

Figure 4: Distribution of press releases

Table 1: Summary statistics of text length

source	n	mean	sd	median	min	max
News articles						
Bild.de	1303	476.07	318.28	398.0	121	3710

Press releases						
AfD	523	212.83	72.16	196.0	103	553
B90/GRÜNE	211	229.32	63.37	219.0	104	399
CDU	248	274.54	106.08	256.0	100	1030
DIE LINKE	686	200.47	71.78	190.0	101	1048
FDP	301	161.90	83.78	144.0	100	999
SPD	315	213.41	56.16	208.0	103	429

Table 1 illustrates that on average, news articles are longer than the parties' press releases.¹¹ While for news articles the average is between 394 (FOCUS Online) and 590 (Handelsblatt), with press releases the range is between 162 (FDP) and 275 (CDU). The article with the most words (14.507) was published by DIE WELT - the longest press release has 1.048 words and was published by DIE LINKE.

Text pre-processing

To use text as data for statistical analysis, different pre-processing steps have to be conducted. In fact, in order to use text as data and reduce the dimensionality to avoid unnecessary computational complexity and overfitting, pre-processing the text is a central task in text mining (M. Gentzkow, Kelly, and Taddy (2017), Bholat et al. (2015)). Intuitively the term frequency (tf) of a word is a measure of how important that

¹¹News articles with less than 120 words were filtered out in advance, as these were mostly reader comments. Similarly press releases with less than 100 words were filtered out.

word may be for the understanding of the text. To visualize these terms, word clouds are a commonly used technique in text mining as they translate the tf into the size of the term in the cloud. As can be seen in [Figure 5](#), problems arise with words that are highly frequent. For example “die,” or “der” (eng. “the”), “und” (eng. “and”), and “ist” (eng. “is”) are extremely common but unrelated to the quantity of interest. These terms, often called stop words ([M. Gentzkow, Kelly, and Taddy 2017](#)), are important to the grammatical structure of a text, but typically don’t add any additional meaning and can therefore be neglected.

Figure 5: Wordcloud before pre-processing

To remove distorting words, the pre-defined stop word list from the Snowball project¹² is used together with a customized, domain-specific list of stop-words. Additionally punctuation character (e.g. ., ,, !, ?, etc.) and all numbers are removed from the data. A next step to reduce the dimensionality of text data is to apply an adequate stemming technique. Stemming is a process by which different morphological variants of a word are traced back to their common root. For example, “voting” and “vote” would be treated as two instances of the same token after the stemming process. There are many different techniques for the stemming process. I apply the widely used Porter-Stemmer algorithm, which is based on a set of shortening rules that are applied to a word until it has a minimum number of syllables.¹³

As an example, the following word clouds represent the most frequent words of the pre-processed articles for Bild.de (Figure 6(a)) and press releases of AfD (Figure 6(b)). It becomes evident that these are texts discussing domestic policy issues. The SPD in particular seems to be highly frequent for Bild.de.

The next step is to divide the entire data set into individual documents and to represent these documents as a finite list of unique terms. In this setting, each news article and each press release represents a document d , whereby each of these documents can be assigned to a news website or a party. The sum of all documents forms what is called the corpus. For each document $d \in \{1, \dots, D\}$ the number of occurrences of term v in document d is computed, in order to obtain the count $x_{d,v}$, where each unique term in the corpus is indexed by some $v \in \{1, \dots, V\}$ and where V is the number of unique terms. The $D \times V$ matrix \mathbf{X} of all such counts is called the document-term matrix. Each row in this matrix represents a document, where each entry in this row counts the occurrences of a unique term in that document. Table 2 provides a sample output of the document-term matrix used in this paper, where each document is represented by a unique id (the row name in the example below). This representation is often referred to as the bag of words model (M. Gentzkow, Kelly, and Taddy 2017), since the order in which words are used within a document is disregarded.

¹²<http://snowball.tartarus.org/algorithms/german/stop.txt>

¹³<https://tartarus.org/martin/PorterStemmer/>

topic-word distributions (ϕ). This way, STM offers a method of ‘structuring’ the prior distributions in the topic model, including additional information in the statistical inference procedure, while LDA assumes that $\theta \text{ Dirichlet}(\alpha)$ and $\phi \text{ Dirichlet}(\beta)$, where α and β are fitted with the model.

In order to include the covariates in the statistical inference procedure, two design matrices of covariates (X and Z) are specified, where each row defines a vector of covariates for a specific document. In X , the covariates for topic prevalence are given, so that the probability of a topic for each document varies according to X , rather than resulting from a single common prior. The same applies to Z , in which the covariates for the word distribution within a topic are specified. The underlying data generating process to generate each individual word $w_{d,n}$ in a document d for the n^{th} word-position can be described as follows:

- for each document i , draw its distribution of topics θ_d depending on the metadata included in the model defined in X ;
- for each topic k , draw its distribution of words ϕ_k depending on the metadata included in the model defined in Z ;
- for each word n , draw its topic z_n based on θ_i ;
- for each word n , draw the term distribution for the selected topic $\phi_{z_{d,n}}$.

One crucial assumption to be made for topic models like LDA or STM is the number of topics (K) that occur over the entire corpus. There is not a “right” answer to the number of topics that are appropriate for a given corpus (Grimmer and Stewart 2013). M. Roberts, Stewart, and Tingley (2016b) propose to measure topic quality through a combination of semantic coherence and exclusivity of words to topics. Semantic coherence is a criterion developed by Mimno et al. (2011) and is closely related to pointwise mutual information (D. Newman et al. 2010): it is maximized when the most probable words in a given topic frequently co-occur together.

Using the function *searchK* from the *stm* package several automated tests are performed to help choose the number of topics including the average exclusivity and semantic coherence as well as the held out likelihood (Wallach, Mimno, and McCallum 2009) and the residuals (Taddy 2012). This process revealed that a model with 40 topics best reflects the structure in the corpus. Furthermore, I use the author and bi-week dummies of a document as topical prevalence variable. In other words, I assume that the probability of a topic to be included in a news article or a press release depends on the author of that document and when it was published. I argue that these variables are best suited to capture temporal and publisher level variation in the documents.

```
## stm(documents = news_df_sparse, K = 40, prevalence = ~source +
##       s(year_biweek), data = covariates, init.type = "Spectral")
```

In general inference of mixed-membership models, such as the one applied in this paper, has been a thread of research in applied statistics Braun and McAuliffe (2010). Topic models are usually imprecise as the function to be optimized has multiple modes, such that the model results can be sensitive to the starting values (e.g. the number of topics and the covariates influencing the prior distributions). Since an ex ante valuation of a model is hardly possible, I compute a variety of different models and compare their posterior probability. This enables me to check how results vary for different model specifications (M. Roberts, Stewart, and Tingley 2016a). I then cross-checked some subset of assigned topic distributions to evaluate whether the estimates align with the concept of interest (M. Gentzkow, Kelly, and Taddy 2017).

Results of the STM

As mentioned in the previous section, the generative process of the STM results in a topic distribution θ_d for each document d over all topics k and a word distribution ϕ_k for each topic over all terms in the vocabulary. The most probable words of each topic may help to understand what each topic is about.¹⁵ However, since those most probable words are not necessarily the most exclusive words and they only represent a small fraction of the probability distribution, interpretation should be done very cautiously.

¹⁵Table 9 gives an overview of the most probable terms for each topic.

For our analysis, we use the topic distribution of each document to estimate the similarity of documents. Figure 7 illustrates such a topic distribution of two news paper articles. The red numbers display the topic probability (for probabilities ≥ 0.02). News article 1¹⁶ shows a clear distribution towards topic 36, for which terms like Bundeswehr, Soldaten (soldiers), Nato, Verteidigungsministerin (defense minister) are among the most probable words. News article 2¹⁷ does not show such a clear tendency towards a single topic. Topic 40, 18 and 5 are within a comparable range. However, for all three topics similar terms are among the top terms.

Similarly as for the news articles, Figure 8 illustrates the topic distribution for two press releases randomly chosen from the corpus. For press release 1¹⁸ topic 24 is the most probable topic which contains terms about the G20 Summit, during which left-wing radicals caused considerable riots. Topic distribution of press article 2¹⁹ shows peaks for topic 6 and 35. Top terms of topic 6 contain the words trump, us, usa, deutschland (Germany) and präsident (president). Similarly topic 35 seems to deal with German foreign policy, since top terms include words like eu, deutschland (Germany), europa and bundesregierung (Federal Government).

Figure 7: Topic probability of sample news articles

Figure 8: Topic probability of sample press releases

Since the source and publication date is known for each document, the probability of certain topics can be analysed, aggregated by this metadata. The left chart of Figure 9 is showing the 15 topics with the highest probability for press releases published by the AfD. The right side of the figure is aggregating the probability

¹⁶Bundeswehr scandal: ex-commander attacks Von Der Leyen

¹⁸Lars Herrmann: The danger for Germany and its Basic Law is also coming from the left

¹⁹Trump chooses the path to isolation

by source and time (in weeks) for two sample topics, displaying how they change over time in the AfD press releases compared to two sample news papers. It becomes clear, that topic 9²⁰ is systematically more likely in the AfD's press releases compared to the two newspapers. There is a noticeable increase in probability during the election campaign period and ends in a peak on election day itself. For Handelsblatt and Bild.de, too, a slight increase around election day is discernible and the probability of this topic shows some peaks for Bild.de both before and after the election. The top words of Theme 38²¹ suggest that it addresses refugees - a topic the AfD has a very clear position on. The probability of this topic increases in the AfD's press releases until about a month before the election and then levels off somewhat. A similar trend can be seen for the news articles from Bild.de. The curve from Handelsblatt is rather flat and shows no apparent difference between before and after the election.

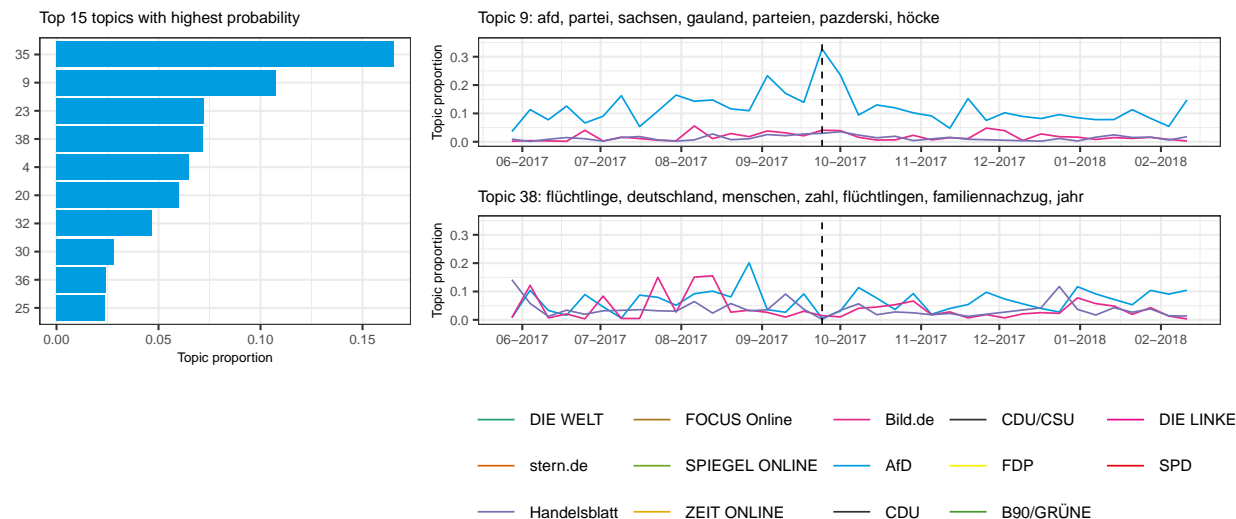

Figure 9: Comparison of topic probability - sample topics AfD

Figure 10 is doing a similar analysis for the aggregated topic distribution in press releases of the FDP. The chart on the left illustrates that, as in the case of the AfD, the topic 35 has the highest probability in the press releases of the FDP. Unlike in the case of the AfD, however, this is followed by topics that have clearer temporal peaks, as shown on the right using two example topics. Topic 10²² has a clear peak for both the news papers and the FDP press releases around August 2017. At that time, there was a debate about whether and where driving bans for diesel cars would be introduced. After the states of Baden-Württemberg and North Rhine-Westphalia initially filed a lawsuit against this, the court proceedings that would decide whether driving bans are permissible began in mid-February 2018. The temporal curve of the FDP shows a further increase in topic probability at this time, which can also be detected at Handelsblatt. At Bild.de, however, the topic is apparently only taken up once briefly in August 2017, as only a very low topic probability can be seen thereafter. The peak of the probability of topic 39²³ in all three sources right after the election is reflecting the exploratory talks on the possible formation of a Jamaica coalition, which officially failed on November 19, 2017 after the FDP announced its withdrawal from the negotiations.

Cosine similarity

Next, the cosine similarity measure is used in order to compare the retrieved topic distribution of documents. Cosine similarity is a measure for the distance between two vectors and is defined between zero and one; values towards 1 indicate similarity. As topic proportions per document are vectors of the same length, the

²⁰translation: afd, party, saxony, gauland, parties, pazderski, hücke

Figure 10: Comparison of topic probability - sample topics FDP

cosine similarity allows a comparison of the topic distribution between two documents.²⁴

$$CS = \cos(\theta) = \frac{a * b}{||a|| ||b||}$$

For example, Table 3²⁵ displays the most similar documents of the document with the title *Parteitag, Koalitions-Krimi, Ur-Wahl - Woran kann die GroKo jetzt noch scheitern?* (Bild.de).²⁶

Table 3: Most similar documents

title	source	cos_sim
Asylzahlen 2017 - schwarz-rot führt Obergrenze durch die Hintertür ein	DIE LINKE	0.542
Jörg Meuthen: Nicht neue GroKo, sondern LoKo – Loser Koalition	AfD	0.522
Rentenpläne von Union und SPD schlimmer als erwartet	FDP	0.478
Union und SPD stabilisieren die krasse soziale Ungerechtigkeit in diesem Land	DIE LINKE	0.401
Jürgen Pohl: Union und SPD verabreden Politik zu Lasten von Rentnern und Ostdeutschen	AfD	0.388

In the next step, for each news paper, the cosine similarity between all topic-document distribution pairs between the news papers articles and the press releases is calculated if that press releases was published within 7 days before the publication date of the news article. This means the topic distribution of news article 1 is compared to press release 1, 2, 3 and so on as long as the press release was published within 7 days before the news article. Table 4 illustrates a sample subset of the data for DIE WELT.

²⁴For applications of cosine similarity to compare of topic model outcomes see e.g. Rehs (2020) and Ramage, Dumais, and Liebling (2010)

²⁵Translations: 1) Asylum figures 2017 - black-red (synonym for GroKo) introduces upper limit through the back door (DIE LINKE) 2) Jörg Meuthen: Not a new GroKo, but LoKo - Loser Coalition (AfD) 3) Pension plans of Union and SPD worse than expected (FDP) 4) Union and SPD stabilize the extreme social injustice in this country (DIE LINKE) 5) Jürgen Pohl: Union and SPD agree on policy at the expense of pensioners and East Germans (AfD)

²⁶Translation: Party conference, coalition thriller, primal election - what can fail the GroKo now? (Bild.de)

Table 4: Dataset structure step 1 - DIE WELT

title1	title2	cosine_sim	source1	source2	date1	date2

Zu hohe Zuwanderu...	Soziale Sicherhei...	0.27	DIE WELT	B90/GRÜNE	2017-10-11	2017-10-09

Next, the mean cosine similarity for each news article publication date (date1) and party (source2) is estimated to obtain the final data frame (see Table 5).

Table 5: Final dataset structure - DIE WELT

date1	source1	source2	cos_sim
2017-09-25	DIE WELT	DIE LINKE	0.10
2017-08-09	DIE WELT	SPD	0.06
2017-08-11	DIE WELT	DIE LINKE	0.22
2017-07-01	DIE WELT	SPD	0.06
2017-09-14	DIE WELT	SPD	0.13

V Model estimations

To get a first idea of the trend of the data over time, the mean cosine similarity between the news articles and each parties press releases conditional on the day can be plotted. Figure 11 shows that kind of plot for Handelsblatt and Bild.de (See Figure 13 for all news papers). Based on these figures, a few observations can be made. The similarity with the FDP, e.g., seems to increase over time for both Handelsblatt and Bild.de. In the case of Bild.de, this applies to all parties, except for the AfD, where a slight downward trend is discernible.

Figure 11: Log of daily mean cosine similarity between newspaper/press articles pairs

OLS dummy regression

To measure whether there is a significant difference in the topic similarity for each party for a news publisher, a simple OLS regression is estimated, where the similarity score ($\ln(CS_i)$) on day i between the news articles of that news publisher and the press releases of a political party k is the dependent variable and the political party dummies are the independent variables.

$$\ln(\text{CS}_i) = \beta_0 + \beta_n D_{i,k-1} + \epsilon_i,$$

with $i = \text{date}^{27}$, $k = \text{political party}^{28}$

Table 6 display the result of that estimation. Since the dependent variable is log transformed, the the % impact of D on Y can be estimated as $\exp(\beta) - 1$. E.g. since the transformed coefficient for $D_{B90/GRÜNE}$ is -0.2067 , a switch from from 0 to 1 can be interpreted as a 21% decrease of topic similarity for B90/GRÜNE compared to AfD (the base dummy group), holding everything else equal. Or, in other words: Compared to AfD, the similarity of topics of DIE WELT and B90/GRÜNE is 21% lower. In general, for all news papers (except for Handelsblatt) the topic similarity is significantly less between the news articles of that news paper and press releases of political parties when compared to press releases of the AfD.

Regression discontinuity model

We assume that news paper report differently during election campaigns and that the election day introduces a change in the reporting. The assumption, that news papers report differently before elections (during election campaigns) coincides with the basic idea of regression discontinuity design (RDD). Therefore, a RDD is applied to identify the short-term effect of the election on the topic similarity between news paper articles and press releases. The RDD was designed by [Thistlethwaite and Campbell \(1960\)](#) and formalized by [Hahn, Todd, and Van der Klaauw \(2001\)](#) to measure the effect of a treatment in a nonexperimental setting, where the treatment defined as discontinuous function of a continuous, observed variable (the ‘running’ or ‘forcing’ variable). Like [Thistlethwaite and Campbell \(1960\)](#), who estimated the effect of receiving the National Merit Scholarship on future academic outcomes, early studies that rely on RD designs estimate the effects of certain thresholds of a running variable on educational outcomes (i.e. financial aid (([van_der_klaauw_estimating_2002?](#))) or class size (([angrist_using_1999?](#)))). Following these early studies in the area of education, the RDD has received attention in a wider range of the economic literature, including labor economics, political economy, health economics, and environmental economics. Compared to alternative quasi-experimental estimators like difference-in-difference and matching techniques, RDD is considered as the estimator with the greatest internal validity (([lee_regression_2010?](#))).

In our model, the running variable W is the time difference between date i and the election date (in days) and the cutoff point c is the election day. We use a sharp RDD, where the probability that an individual

²⁷date1 in [Table 5](#)

²⁸source2 in [Table 5](#)

receives a treatment jumps from 0 to 1 at the cutoff (i.e. at the threshold $W_i = c$).²⁹

The visual representation of the treatment effect for the two sample new publisher Handelsblatt and Bild.de in Figure 12 reveals that the topic similarity for Handelsblatt decreases after the election for CDU, FDP and B90/Grüne. A less clear to no effect can be seen for SPD, DIE LINKE and AfD. In contrast, the treatment effect at Bild.de seems to exist only for the AfD (see Figure 14 for all news publisher).

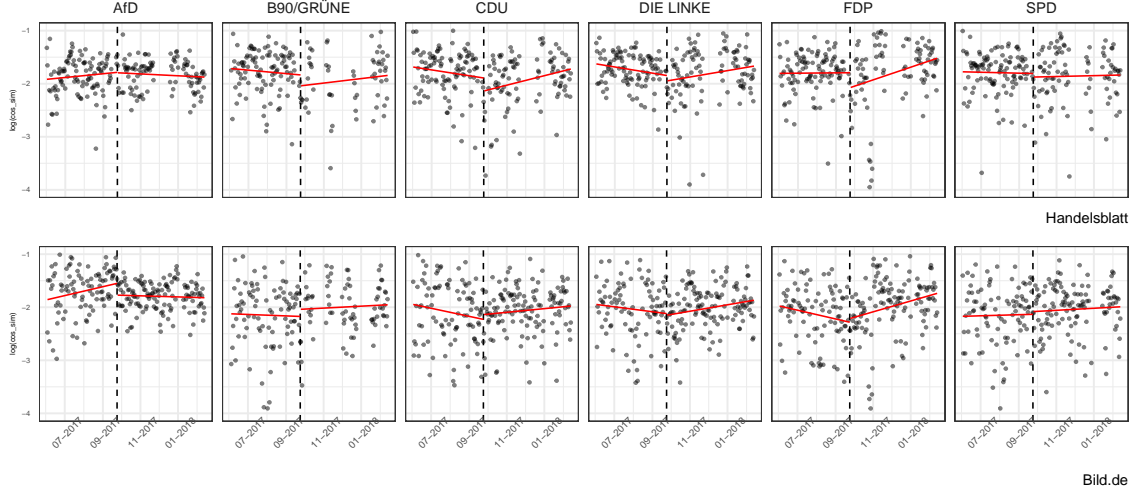

Figure 12: Log of mean cosine similarity between newspaper/press articles pairs - with cutoff value

In order to statistically evaluate this observations, for each news paper the following model is estimated.

$$\ln(\text{CS}_i) = \beta_0 + \beta_1 T_i + \beta_2 W_i + \beta_3 D_{i,k-1} + \beta_4 T_i D_{i,k-1} + \epsilon_i$$

where

$$T_i = \begin{cases} 1, & \text{if date} \geq \text{election date} \\ 0, & \text{if date} < \text{election date} \end{cases}$$

such that the receipt of treatment T_i is determined by the threshold c (election day) of the continuous (running) variable W_i and β_1 is the average treatment effect for observations with $W_i = c$. In other words, β_1 gives the average change of the similarity between the content of news articles and press releases after the election day.

Including interaction terms $T_i D_{i,k-1}$ and since we are estimating an isolated model for each newspaper β_4 gives the average treatment effect for each newspaper/party pair (i.e. how much the slope changes for each party).

Example interpretation for *Bild.de* (see Table 7)

The coefficient β_4 for $D_{SPD} = 1$ shows the difference of the treatment effect for SPD. To illustrate this, we can compare the model equation for $D_{SPD} = 1$ and $D_{SPD} = 0$

$$\begin{aligned} D_{SPD} = 1: \quad \ln(\text{CS})(D_{SPD} = 1) &= -1.647 + (-0.189)T + (0.001)W - 0.479 + (0.252)T \\ \ln(\text{CS})(D_{SPD} = 1) &= -2,126 + (0.001)W + (0.252 - 0.189)T \end{aligned}$$

$$\begin{aligned} D_{SPD} = 0: \quad \ln(\text{CS})(D_{SPD} = 0) &= -1.647 + (-0.189)T + (0.001)W \\ \ln(\text{CS})(D_{SPD} = 0) &= -1.647 + (0.001)W + (-0.189)T \end{aligned}$$

- When D_{SPD} switches from 0 to 1, the treatment effect increases by 0.252.

²⁹In the other design - the fuzzy RDD - the probability that an individual receives a treatment increases discontinuously from a to b (where $0 < a < b < 1$) at the threshold $W_i = c$.

Note:

*p<0.1; **p<0.05; ***p<0.01

To interpret this coefficient, we have to transform it (our dependent variable is log transformed).

For $D_{SPD} = 0$: $\exp(-0.189) - 1 = -0.172$

After the election day the topic similarity between *Bild.de* and AfD decreased by ~17.2%

$D_{SPD} = 1$: $\exp(-0.189 + 0.252) - 1 = 0.065$

After the election day the topic similarity between *Bild.de* and SPD increased by ~6.5% compared to AfD.

General interpretation:

- News articles of *DIE WELT* and *Bild.de* show a significant decrease of topic similarity with AfD after the election. No such effect can be found for the other news papers.
- News articles of *Handelsblatt* are significantly less similar with B90/G & CDU after the election (compared to AfD). The opposite is true for *Bild.de* where new articles are more similar to ALL party press releases (except for DIE LINKE) when compared to AfD.

The results show, that for some news papers (*DIE WELT* & *Bild.de*), there is a significant change in the topic similarity between their news articles and the press releases of parties.

VI Discussion and conclusion

This paper investigates whether political reporting of news papers is similar for all political parties. Results show, that the news articles of all news papers (except for *Handelsblatt*) are significantly more similar to press releases of the AfD than any other party.

Furthermore, it was assumed, that this reporting differs between periods of election campaign. The results show a significant effect of the switch between “before” election (election campaign period) and “after” election for some news papers.

- For *DIE WELT* and *Bild.de* the election date has a significant effect on the similarity with the AfD:
The similarity between news articles and press releases of AfD decreases
